Below is the use case for a user who would like to use the search function in our website. They will begin by entering the keywords, their query. This query will be sent to be searched from the data base, in which case SQL will return any relevant books. The relevant books will then display on the page as the search results. Should the user want to view a specific book in more detail, they can click "View". On this viewing page, the end user can see information such as availability, price, title, etc. of the book. The SQL database will return all the books information to be displayed on the dynamic webpage.
